■ [New and Changed Metadata Types](#)

■ [Salesforce Scheduler Videos](#)

To understand the reasoning behind the output of an expression set that has Decision Explainer enabled, capture action logs each time the expression set is run from Salesforce Flow. To simulate an expression set version that has a large number of input variables, pass the variable values in JSON format. Export decision matrix versions to DMN files and reuse them outside Business Rules Engine.

- [Unified Analytics Experiences](#)
Export Decision Matrix Versions for Reuse Outside Business Rules Engine

Make it easier to collaborate on business decisions by exporting decision matrix versions to Decision Model and Notation (DMN) files. DMN is a standardized specification for writing business rules. With DMN files, you can reuse a matrix version created in Business Rules Engine in any tool that supports DMN files. This release supports exporting matrix versions to DMN files only through connect APIs. The exported files can be downloaded from a decision matrix version's record detail page in the Business Rules Engine app.

- **Use Currency and Date/Time Data Types in Decision Tables**

Create a wider range of rules in decision tables using the Currency and Date/Time data types. With the support for the Currency data type, you can now look up decision tables that use the Currency data type from expression set versions.

- **Clone Expression Sets**

If you want to modify an expression set's versions without affecting the original expression set, clone the expression set. Cloning an expression set clones all the versions in the expression set. You can copy the versions of an expression set that's used as a subexpression in another expression set or is referenced in a flow, without breaking the calling expression set or flow.

- **Capture Action Logs for Expression Sets Called from Salesforce Flow**

When a flow calls an expression set that has Decision Explainer enabled, action logs are now generated for every run of the expression set. Action logs show the rationale behind the expression set's output. To capture action logs, you specify the record ID of the object for the __actionContextCode parameter, and the explainability action definition or the purpose for which the expression set is used for the __specName parameter.

- **View Business Elements as First-Level Elements in Expression Set Builder**

Business elements shipped with your cloud are now listed as first-level elements and look like standard step elements. Previously, you had to add a business element as a step on the builder canvas, and then search for and select the business element from the available list.

- **Simulate Expression Set Versions Using JSON Input**

Want to simulate an expression set version that has a large number of input variables? You can now pass the input data in JSON format using the Advanced input mode for simulation. With the Advanced input mode, you can enter the input values in the JSON input text area. Previously, all the input variables in the version only appeared as fields, and you entered values for each field. The JSON input option simplifies and speeds up the

process of passing input variables, especially when you have a large number of values to input. ■ [Einstein Discovery](#)
